## Critical Flaws in VNC Threaten Industrial Environments

Author:

Some of the most critical industrial environments are those that rely on VNC for remote access.

According to researchers at Kaspersky, they potentially affect 600,000 web-accessible servers in systems that use the code.

The research looked into four popular VNC-based systems, LibVNC, UltraVNC, TightVNC1.X and TurboVNC, which are actively used in automated industrial facilities to enable remote control of systems, according to the firm. Approximately 32 percent of industrial network computers having some form of **remote administration tools**, including VNC.

"The prevalence of such systems in general, and particularly ones that are vulnerable, is a significant issue for the industrial sector as potential damages can bring significant losses through disruption of complex production processes," Kaspersky researchers wrote in an analysis of the bugs for ICS CERT, **released Friday**.

Kaspersky found vulnerabilities not only in the client, but also on the server-side of the system; many of the latter however can only be exploited after password authentication. Across all 37 bugs, there are two main attack vectors, the firm said: "An attacker is on the same network with the VNC server and attacks it to gain the ability to execute code on the server with the server's privileges; [or] a user connects to an attacker's 'server' using a VNC client and the attacker exploits vulnerabilities in the client to attack the user and execute code on the user's machine."

A significant number of the problems detailed in the research were found and reported last year; however, each of the projects examined also had newly discovered bugs.

For instance, a newly found critical (9.8 out of 10 on the CVSS v.3 severity rating scale) database stack buffer overflow vulnerability in the TurboVNC server code could result in RCE. The issue (**CVE-2019-15683**) exists because the stack frame is not protected with a stack canary. However, to exploit the bug, authorization on the server is required.

"Some compilers perform...optimizations by removing stack canary checks from the functions that don't have explicitly allocated arrays," according to the research. "However, the compiler could make a mistake and fail to check for the presence of a buffer in some of the structures on the stack or in switch-case statements."

Also, a critical integer-overflow vulnerability (**CVE-2018-15361**) exists in UltraVNC client-side code. This is also critical, with a CVSS rating of 9.8 of denial-of-service state. Researchers also "wouldn't r

right parameters, a remote attacker would be able to write a null byte to the `_NT_HEAP` structure, which will be located directly before a huge chunk.”

Meanwhile, the [CVE-2019-8262](#) critical vulnerability (with a CVSS score of 9.8 out of 10) was identified in the handler of data encoded using the UltraVNC encoding function that could cause information disclosure.

“The uninitialized variable `new_len` is passed to the `lzo1x_decompress` function,” according to the research. “At the time of calling the function, the variable should be equal to the length of the `m_zlibbuf` buffer...since the variable `new_len` was not initialized, it contained a large text section address value. This made it possible for a remote user to pass specially crafted data to the decompression function as inputs to ensure that the function, when writing to the `m_zlibbuf` buffer, would write the data beyond the buffer’s boundary, resulting in heap overflow.”

In TightVNC code version 1.3.10, there’s a critical global buffer overflow ([CVE-2019-8287](#)) in `HandleCoRREBBP` macro function, also with a CVSS rating of 9.8 out of 10. This can also potentially result RCE, Kaspersky found.

Researchers also recently found a high-severity flaw in LibVNC ([CVE-2019-15681](#)), with a CVSS rating of 7.7 out of 10. It involves a memory leak exploitable via network connectivity in the VNC server code, which allows an attacker to read stack memory and can be abused for information disclosure. According to the advisory, combined with another vulnerability, it can be used to leak stack memory and bypass ASLR.

Worryingly, some of the bugs had been incorporated into the VNC code for years, meaning that projects built on it have “inherited” the issues.

“I was surprised to see the simplicity of discovered vulnerabilities, especially considering their significant lifetime,” said Pavel Cheremushkin, Kaspersky ICS CERT vulnerability researcher, in a media statement. “This means that attackers could have noticed and taken advantage of the vulnerabilities a long time ago. Moreover, some classes of vulnerabilities are present in many open-source projects and remain there even after refactoring of the [main] codebase.”

Kaspersky contacted the affected developers, and patches have been issued for supported products, it said. TightVNC for instance has discontinued the development of the TightVNC 1.X line and considers it end of life, so the bugs won’t be patched.
